Q1 Ideation: AI Agents for PM/TPM Productivity at Nexora Pvt. Ltd. capstone, Applied Agentic AI for PMs/TPMs

Nexora's PMs and TPMs run several projects at once with very few people. The three use cases below target the largest time sinks named in the problem statement. Each uses a specialist agent that works only from project files and is reviewed by a PM before anything is shared. Mira, the system built in Q2, implements all three.

Use case 1: Project plan generation

Pain point. A plan built from a high-level description takes 3 to 4 hours of manual work per project, and every PM uses a different format.

Agentic solution. A Planner agent, reached through a router, reads the project description and timeline and drafts phases, key activities, milestones, deliverables and a timeline. If the request is too thin ("we want a chatbot"), it asks for scope, goals, timeline and team size instead of inventing a plan. The PM approves the draft before it is shared.

Inputs and outputs. Inputs: project description (text), timeline (CSV), the PM's request. Output: a structured plan in one standard template, with the source files named.

Success metrics.

- Time to first draft: from 3 to 4 hours down to under 20 minutes including PM review (the PM times the first five projects).
- Grounding: 0 goals or milestones that are not in the source files, checked against the description and timeline.
- PM acceptance: at least 80% of plan sections kept without a rewrite (from the approval log).

Knowledge base. Project description, project timeline, Nexora's plan template, and later a library of approved past plans.

Use case 2: Risk assessment

Pain point. Risk assessments are inconsistent: some projects have a detailed risk matrix and others have none, so risks surface late.

Agentic solution. A Risk Assessor agent builds a categorised risk matrix (description, impact, mitigation) using only risks from the project's risk register, and links each to the task board where it can. For a vague request ("new project starting soon") it asks for project details instead of inventing risks. An LLM judge scores risk relevance, and the PM approves the result.

Inputs and outputs. Inputs: risk register (CSV), project description, task board (CSV). Output: a categorised risk table with risk ID, category, impact, mitigation and the reason each risk matters now.

Success metrics.

- Coverage: 100% of Nexora projects get a risk assessment in the same format, against inconsistent coverage today.
- Grounding: 0 risks or task IDs that are not in the register or the board (a code check on IDs).
- Judge reliability: at least 80% pass/fail agreement between the LLM judge and a human reviewer (Mira's calibration measured 58% to 68%, so human review stays in place until this is met).

Knowledge base. Project risk register, Nexora's risk category list, a library of standard mitigations, and the task board.

Use case 3: Weekly status report and milestone alerts

Pain point. Weekly status reports take 1 to 2 hours to compile by hand from the task board and meeting notes, and missed milestones are found only in retrospectives.

Agentic solution. A Status Reporter agent counts tasks by status in code (not in the model) and writes the report: done, in progress, to do, blocked, upcoming milestones and overall health. A Milestone Tracker compares the timeline with progress as of a given date and flags blocked tasks, at-risk tasks and milestones that fall inside the next two weeks, with the reason for each. The PM approves the report by email before it goes out.

Inputs and outputs. Inputs: task board (CSV or API), project timeline, an as-of date. Outputs: a standard weekly status report and a short list of blocked and at-risk items and upcoming milestones.

Success metrics.

- Time to compile: from 1 to 2 hours down to under 15 minutes including PM review.

- Accuracy: task counts match the board in 100% of reports (checked against the board export).
- Early warning: every blocked or at-risk task is flagged before its due date, and the number of milestones missed without a prior alert falls to 0.

Knowledge base. Task board export (later a Jira or Trello API), project timeline, the status report template, and the written rules for "at risk" and "watch".

Why these three

They cover the three recurring outputs the problem statement names (plan, risk assessment, status report), they all rely on structured project files that Nexora already has, and each can be checked against those files. The time and acceptance targets above are proposals to measure during rollout. What Mira has measured so far is grounding and cost: it passed the 12 baseline tests in each of Runs 2 to 5 with no hallucinations, at about $0.0003 per request.
